I. INTRODUCTION

Firehose (FH) and Mirror Mode (MM) instabilities are both pressure anisotropic instabilities, which mainly happen in high beta plasma, and have many applications in space and astrophysical physics. One (FH) happens when parallel pressure exceeding perpendicular one, and the other (MM) happens when perpendicular pressure exceeding parallel one. Both of these two modes have been discussed in literatures by many authors. The basic properties of them can also be found in textbooks or monographs, see e.g., [8] and [30].

Mirror mode (MM) instability was identified and discussed since [25], where the MHD theory is used, which is only suitable for long wavelength limit. [29] gives a kinetic description, and shows that this mode is not a simply fluid instability. [6] put forward to both the effects of finite Larmor radius (FLR) and nonuniform, i.e., drift-mirror mode. [27] gives a discussion of the physical mechanism of the linear mirror instability in cold electron temperature limit. Recently, series papers by Pokhotelov *et al* addressed many details of MM via both fluid theory and kinetic theory, such as finite electron temperature effects [14], non-Maxwellian velocity distribution [16], finite ion-Larmor radius wavelengths [18, 19]. Gyrokinetic theory and simulation are introduced to discuss linear and nonlinear MM by Qu *et al*, [20–22].

Firehose instability is another well-known plasma instability, which is in fact from the same branch of the kinetic Alfven wave (KAW), hence, we will not distinguish them in the following sections. When isotropic but with FLR, we get KAW [7, 9]; while, when anisotropic but using long wavelength limit, we get the classical FH [3, 13, 24]. It is found by [31] (also a review paper [32]) that a significant new effect which had been neglected in the past will be brought in when allowing the ion gyroradius to be finite. [4] extends [31] to discuss electron temperature anisotropy effects.

FH and MM have been discussed in almost the same approaches due to their similarities, e.g., CGL fluid, kinetic corrections. However, most the analytical solutions are reduced to just including one of them, and then, there are few discussions of coupling effects. For examples, when mirror mode is unstable, where is the FH (KAW) solution? Can FH be also excited to unstable? Can FH bring MM from a pure damping/growth mode to with real frequency? [26] just discusses the nonlinear growth of FH and mirror fluctuations, mainly via simulation. [5] has discussed the coupling indeed, but uses the fluid theory then not general. The gyrokinetic treatment of the stability of coupled Alfvén and drift mirror modes in nonuniform plasma can be found in [11, 12], however, where FLR effects are neglected.

Here, we talk about linear coupling effects to answer the above questions. Firstly, a general anisotropic (bi-Maxwellian) 3-by-3 dispersion relation matrix is derived in gyrokinetic framework (then, with FLR effects but only for $k_\parallel/k_\perp \ll 1$) in Sec.II. In Sec.III, we show the gyrokinetic dispersion relation can reproduce the FH and MM solutions. In Sec.IV, using only cold electron assumption $T_e/T_i \ll 1$, the matrix is reduced to 2-by-2 for discussion the coupling of FH and MM. The dispersion relation is solved both analytical and numerical, and is also compared with the full-kinetic code WHAMP (Waves in Homogeneous Anisotropic Multicomponent Magnetized Plasma, [23]). General stability properties for arbitrary Larmor radius at the $(\beta_\parallel, \beta_\perp)$ plane are made clearly from both analytical and numerical solutions and are also confirmed by Nyquist analysis in Sec.V. A summary is drawn in the last section. Appendix gives some detailed discussions of the gyrokinetic dispersion matrix.

II. GYROKINETIC DISPERSION RELATION MATRIX

Here, we use the gyrokinetic (GK) theory [1] instead of the full kinetic (FK) theory to calculate the general dispersion relation matrix, which excludes the high frequency (Ω_{ci}) modes automatically. The linear GK or-

dering is

1. Small amplitude: $\delta f/F_0 \sim e\delta\varphi/T \sim \delta B/B_0 \sim \delta \ll 1$;
2. Low frequency: $\omega/\Omega_i \sim \delta$;
3. Anisotropic: $k_\parallel/k_\perp \sim \rho_i/L_0 \sim \delta,\ k_\perp\rho_i \sim 1$.

For detailed discussion of the gyrokinetic assumptions, one can refer to [1] or [10]. We comment here, the same ordering δ used here for all small variables is just for convenience, and the third assumption $k_\perp\rho_i \sim 1$ is not a must.

Electrons and ions are assumed both bi-Maxwellian distribution,

$$F_0 = \frac{1}{\pi^{3/2}\alpha_\perp^2\alpha_\parallel}\exp\left(-\frac{v_\perp^2}{\alpha_\perp^2}-\frac{v_\parallel^2}{\alpha_\parallel^2}\right),\ \alpha_{\perp,\parallel} = \left(\frac{2T_{\perp,\parallel}}{m}\right)^{1/2}. \tag{1}$$

Using the framework of [2], we write the linearized equations of quasi-neutrality condition, vorticity equation (or parallel Ampere's law) and perpendicular Ampere's law to matrix form

$$\overleftrightarrow{C}\begin{bmatrix}\delta\phi_\parallel\\ \delta\psi\\ \frac{\delta B_\parallel}{B_0}\frac{T_{\perp i}}{q_i}\end{bmatrix} \equiv \begin{pmatrix} c_{SS} & c_{AS} & c_{MS}\\ c_{SA} & c_{AA} & c_{MA}\\ c_{SM} & c_{AM} & c_{MM}\end{pmatrix}\begin{bmatrix}\delta\phi_\parallel\\ \delta\psi\\ \frac{\delta B_\parallel}{B_0}\frac{T_{\perp i}}{q_i}\end{bmatrix} = 0. \tag{2}$$

Here, Coulomb gauge $\nabla\cdot\mathbf{A}=0$ is used. $\delta\phi$ is the perturbed electrostatic potential, $\delta\psi = \delta A_\parallel\cdot\omega/ck_\parallel$ is a quantity related to the parallel component of the perturbed magnetic vector potential, and $\delta B_\parallel$ is the parallel component of the perturbed magnetic field. The final dispersion matrix can be gotten as,

$$\overleftrightarrow{C} \equiv \begin{pmatrix} c_{SS} & c_{AS} & c_{MS}\\ c_{SA} & c_{AA} & c_{MA}\\ c_{SM} & c_{AM} & c_{MM}\end{pmatrix}$$
$$= \begin{pmatrix} -\lambda_1+\lambda_2 & -\eta_i\lambda_5 & -\lambda_3-\lambda_4\\ -\eta_i\lambda_5 & \frac{\eta_i b_i}{\bar\omega^2}(1+\Delta)-\eta_i\lambda_5 & \eta_i\lambda_6\\ -\lambda_3-\lambda_4 & \eta_i\lambda_6 & \frac{2\eta_i}{\beta_{\perp i}}-\lambda_7-\lambda_8\end{pmatrix} \tag{3}$$

where,

$$\Delta = \frac{\beta_{\perp i}}{2b_i}(1-\eta_i)\left[1-\Gamma_0(b_i)\right]+\frac{\beta_{\perp e}}{2b_e}(1-\eta_e)\left[1-\Gamma_0(b_e)\right],$$
$$\lambda_1 = \left[1+\xi_i Z(\xi_i)\Gamma_0(b_i)\right]+\tau\left[1+\xi_e Z(\xi_e)\Gamma_0(b_e)\right],$$
$$\lambda_2 = (1-\eta_i)\left[1-\Gamma_0(b_i)\right]+\tau(1-\eta_e)\left[1-\Gamma_0(b_e)\right],$$
$$\lambda_3 = (1-\eta_i)\Gamma_1(b_i)-\frac{\eta_i}{\eta_e}(1-\eta_e)\Gamma_1(b_e),$$
$$\lambda_4 = \xi_i Z(\xi_i)\Gamma_1(b_i)-\frac{\eta_i}{\eta_e}\xi_e Z(\xi_e)\Gamma_1(b_e),$$
$$\lambda_5 = \left[1-\Gamma_0(b_i)\right]+\tau_\perp\left[1-\Gamma_0(b_e)\right],$$
$$\lambda_6 = \Gamma_1(b_i)-\Gamma_1(b_e),$$
$$\lambda_7 = (1-\eta_i)\Gamma_2(b_i)+\frac{\eta_i}{\eta_e\tau_\perp}(1-\eta_e)\Gamma_2(b_e),$$
$$\lambda_8 = \xi_i Z(\xi_i)\Gamma_2(b_i)+\frac{\eta_i}{\eta_e\tau_\perp}\xi_e Z(\xi_e)\Gamma_2(b_e),$$

and,

$$\eta \equiv \frac{T_\parallel}{T_\perp},\ \tau \equiv \frac{T_{\parallel i}}{T_{\parallel e}}, \tau_\perp \equiv \frac{T_{\perp i}}{T_{\perp e}},\ \beta \equiv \frac{8\pi n_0 T}{B_0^2},$$
$$b \equiv \frac{k_\perp^2\rho^2}{2}, \bar\omega^2 \equiv \frac{\omega^2}{k_\parallel^2 v_A^2},$$
$$\delta\phi_\parallel \equiv \delta\phi - \delta\psi\ (E_\parallel = -ik_\parallel\delta\phi_\parallel),$$
$$\Gamma_0(b) = I_0(b)e^{-b},$$
$$\Gamma_1(b) = \left[I_0(b)-I_1(b)\right]e^{-b}, \Gamma_2(b) = 2\Gamma_1(b).$$

where I_n is the first kind modified Bessel function. The dispersion relation is

$$\det\left|\overleftrightarrow{C}\right| = 0 \tag{4}$$

We see from (3), the matrix is symmetrical, i.e., $c_{AS} = c_{SA}$, $c_{AM} = c_{MA}$ and $c_{MS} = c_{SM}$, which is similar with the full-kinetic one (see e.g., [28]). When isotopic ($\eta_{i,e} = 1$), (4) reduces to exactly the same result as [10]. At appendix, we also show that when drop small terms from reduced full-kinetic result in [31], it also gives the same result as this gyrokinetic one.

We can see from (3), the solutions for $\bar\omega$ is independent of $k_\parallel$, which means always $\omega^2 \propto k_\parallel^2$. This is the main drawback of (4) because of that $k_\parallel/k_\perp$ is taken as small term and dropped, then not suitable to discuss the fine structures of the dispersion relation, e.g., the maximum growth rate $\gamma_{\max}$ of mirror mode. However, one can also add the small terms when necessary by comparing with the full-kinetic result (see appendix). For example, [20] adds a $k_\parallel/k_\perp$ term in integral form when discuss mirror mode.

III. SOLUTIONS OF FIREHOSE AND MIRROR MODE

In (3), when only considering one matrix element, $c_{SS} = 0$ gives ions sound wave (ISW, only consider $\delta\phi_\parallel$), $c_{AA} = 0$ gives shear Alfven wave (SAW, only consider $\delta\psi$) and $c_{MM} = 0$ gives mirror mode (MM, only consider $\delta B_\parallel$). $c_{\alpha\beta}(\alpha,\beta = S,A,M)$ is the coupling of each waves.

A. Firehose (KAW) Branch

As mentioned above, $c_{AA} = 0$ represents the firehose and KAW solution,

$$\bar\omega^2 = \frac{b_i}{\lambda_5}(1+\Delta) = \frac{b_i}{\left[1-\Gamma_0(b_i)\right]+\tau_\perp\left[1-\Gamma_0(b_e)\right]}$$
$$\left\{1+\frac{\beta_{\perp i}}{2b_i}(1-\eta_i)\left[1-\Gamma_0(b_i)\right]+\frac{\beta_{\perp e}}{2b_e}(1-\eta_e)\left[1-\Gamma_0(b_e)\right]\right\}. \tag{5}$$

When small Lamor radius $b_e \ll b_i \ll 1$, $\Gamma_0(b) \simeq 1-b+3b^2/4 \simeq 1-b$, (5) reduces to,

$$\bar\omega^2 = 1+\Delta = 1+\frac{\beta_{\perp i}}{2}(1-\eta_i)+\frac{\beta_{\perp e}}{2}(1-\eta_e), \tag{6}$$

which is the classical firehose solution, and when $1+\Delta < 0$, this mode is unstable. When isotropic $\eta_{i,e} = 1$, $\Delta = 0$, (5) reduces to

$$\bar{\omega}^2 = \frac{b_i}{[1-\Gamma_0(b_i)] + \tau_\perp [1-\Gamma_0(b_e)]}, \tag{7}$$

Still using the small Lamor radius assumption to go further, (7) reduces to

$$\bar{\omega}^2 = 1 + 3b_i/4, \tag{8}$$

(8) is the classical KAW solution [7, 9].

B. Mirror Mode Branch

At this case, $c_{MM} = 0$, gives

$$\frac{2\eta_i}{\beta_{\perp i}} - \lambda_7 - \lambda_8 = 0, \tag{9}$$

And, dropping the contributions from electrons (cold electrons assumption) in (9), gives,

$$\xi_i Z(\xi_i) = \frac{\eta_i - (1-\eta_i)\Gamma_1(b_i)\beta_{\perp i}}{\beta_{\perp i}\Gamma_1(b_i)}. \tag{10}$$

(10) is the mirror mode solution. [20] adds a $k_\parallel/k_\perp$ term to (10), then can be used to discuss the $\gamma_{\max}$ of mirror mode, which give the same result as [18] from full-kinetic theory.

IV. COUPLING OF FIREHOSE AND MIRROR MODE

In the above section, we use only one matrix element of the 3-by-3 general dispersion matrix (3), then get kinetic version of both FH (KAW) and MM, which shows accurately enough to discuss single mode by compared with full-kinetic results from previous authors.

At this section, we solve the 2-by-2 matrix to discuss coupling effects of FH and MM. The matrix (3) is general for arbitrary $b_{i,e}$, $\beta_{i,e}$, $\xi_{i,e}$ under the gyrokinetic ordering. When cold electrons ($T_e/T_i \ll 1$), we have $b_e \ll 1$, $\tau, \tau_\perp \gg 1$, $c_{SS} \gg c_{SA}, c_{SM}$, then $\delta\phi_\parallel$ should be very small, which means the parallel electrical field is short circuited (few percents of cold electrons in density is enough, see [8]). We use this only assumption to reduce the 3-by-3 matrix to 2-by-2 for discussion FH and MM coupling.

(4) reduces to,

$$\begin{vmatrix} \frac{\eta_i b_i}{\bar{\omega}^2}(1+\Delta) - \eta_i\lambda_5 & \eta_i\lambda_6 \\ \eta_i\lambda_6 & \frac{2\eta_i}{\beta_{\perp i}} - \lambda_7 - \lambda_8 \end{vmatrix} = 0, \tag{11}$$

where,

$$\begin{aligned}
\Delta &= \frac{\beta_{\perp i}}{2b_i}(1-\eta_i)[1-\Gamma_0(b_i)] + \frac{\beta_{\perp e}}{2}(1-\eta_e) \\
&\simeq \frac{\beta_{\perp i}}{2}(1-\eta_i)(1-\frac{3}{4}b_i), \\
\lambda_5 &\simeq 1-\Gamma_0(b_i) \simeq b_i - \frac{3}{4}b_i^2, \\
\lambda_6 &\simeq \Gamma_1(b_i) - 1 \simeq -\frac{3}{2}b_i + \frac{5}{4}b_i^2, \\
\lambda_7 &\simeq 2(1-\eta_i)\Gamma_1(b_i), \\
\lambda_8 &= 2\xi_i Z(\xi_i)\Gamma_1(b_i) + \frac{2\eta_i}{\eta_e\tau_\perp}\xi_e Z(\xi_e)\Gamma_1(b_e) \\
&\simeq 2\xi_i Z(\xi_i)\Gamma_1(b_i).
\end{aligned} \tag{12}$$

The small b_i expansion is also written in (12) but only used when necessary.

[18] has given a very similar 2-by-2 matrix as (11) via full-kinetic theory, which contains also the small $k_\parallel/k_\perp$ correction. But, it solves only MM by dropping the firehose correction in the mirror approximation $|\omega| \ll |k_\parallel v_{i,\parallel}|$. A fluid theory is used to discuss the instability of mirror mode and firehose in [5], and several stable and unstable regions are given in different parameters space. Since there is no kinetic effect, the results of [5] will be unreasonable. Ignoring FLR effects, [12] gives the gyrokinetic treatment of the stability of coupled Alfvén and drift mirror modes in 1D non-uniform plasma.

For analytical tractable, we solve (11) in long wavelength approximation in this section. This means $b_i \ll 1$. Keep $O(1) + O(b)$, (11) changes to

$$\begin{aligned}
&-\left\{\frac{\eta_i}{\beta_{\perp i}} - [(1-\eta_i) + \xi_i Z(\xi_i)]\right\}\left[\frac{1}{\bar{\omega}^2}(1+\Delta) - 1\right] \\
&= \left\{ \begin{array}{c} \frac{3}{4}\frac{\eta_i}{\beta_{\perp i}} - \frac{3}{4}[(1-\eta_i) + \xi_i Z(\xi_i)] + \\ \frac{3}{2}[(1-\eta_i) + \xi_i Z(\xi_i)]\left[\frac{1}{\bar{\omega}^2}(1+\Delta) - 1\right] - \frac{9}{8}\eta_i \end{array} \right\} b_i
\end{aligned} \tag{13}$$

We use (13) to see the correction from MM to FH and FH to MM.

A. Mirror mode correction to Firehose (KAW)

Look the small FLR correction to firehose solution $[(1+\Delta)/\bar{\omega}^2 - 1] \sim O(b_i)$,

$$\bar{\omega}^2 = \frac{(1+\Delta)}{1 - \frac{\left\{\frac{3}{4}\frac{\eta_i}{\beta_{\perp i}} - \frac{3}{4}[(1-\eta_i)+\xi_i Z(\xi_i)] - \frac{9}{8}\eta_i\right\} b_i}{\left\{\frac{\eta_i}{\beta_{\perp i}} - [(1-\eta_i)+\xi_i Z(\xi_i)]\right\}}}. \tag{14}$$

1. Cold ions

When cold ions, $|\omega| \gg |k_\parallel v_{i,\parallel}|$, $\xi_i = \bar{\omega}/\sqrt{\beta_{\parallel i}} \gg 1$, $\xi_i Z(\xi_i) \simeq -1 - 1/(2\xi_i^2) \simeq -1$,

$$\bar{\omega}^2 = \frac{(1+\Delta)}{1-\frac{3}{8}\left\{\frac{2}{\beta_{\perp i}}-1\right\}b_i\Big/\left\{\frac{1}{\beta_{\perp i}}+1\right\}}$$
$$\overset{\eta_i=1,\ \beta_{\perp i}\ll 1}{\Longrightarrow} \bar{\omega}^2 \simeq 1+\frac{3}{4}b_i \text{ (KAW)} \quad (15)$$

2. Hot ions

Here, we try to see that, when classical FH (KAW) is stable ($1+\Delta > 0$), whether MM can excite it to unstable. When hot ions, $|\omega| \ll \left|k_\parallel v_{i,\parallel}\right|$, $\xi_i = \bar{\omega}/\sqrt{\beta_{\parallel i}} \ll 1$, $\xi_i Z(\xi_i) \simeq i\sqrt{\pi}\xi_i = \bar{\omega}i\sqrt{\pi}/\sqrt{\beta_{\parallel i}} \simeq i\sqrt{\pi}\sqrt{1+\Delta}\text{sgn}(\bar{\omega})/\sqrt{\beta_{\parallel i}}$, (Note: in fact, $\bar{\omega}$ is complex)

$$\bar{\omega}^2 = \frac{(1+\Delta)\left\{\begin{array}{c}\left[A^2-\frac{3b_i}{4}(A-\frac{3}{2}\eta_i)A+(1-\frac{3b_i}{4})B^2\right]\\ -\left[\frac{9}{8}b_i\eta_i B\right]i\end{array}\right\}}{\left[A-\frac{3b_i}{4}(A-\frac{3}{2}\eta_i)\right]^2+\left[(1-\frac{3b_i}{4})B\right]^2}$$
$$= a - isgn(\bar{\omega})b \ \ (a\sim O(1),\ b\sim O(b_i)) \quad (16)$$

where,

$$A \equiv \frac{\eta_i}{\beta_{\perp i}} - (1-\eta_i), B \equiv \frac{\sqrt{\pi}\sqrt{1+\Delta}\text{sgn}(\bar{\omega})}{\sqrt{\beta_{\parallel i}}} \quad (17)$$

Due to $-\text{sgn}(\bar{\omega})$, and provided, $a > 0$, the solutions are always damped.

To find a unstable mode, which means $a < 0$,

$$a<0 \Leftrightarrow \underbrace{(1-\frac{3b_i}{4})A^2}_{>0}+\underbrace{\frac{9}{8}b_i\eta_i A}_{<0}+\underbrace{(1-\frac{3b_i}{4})B^2}_{>0}<0, \quad (18)$$

(18) can only be satisfied when $A < 0$, i.e., mirror mode is unstable. While, if there is a domain satisfy both $a < 0$ and $A < 0$, there must be at least one point satisfy both $a = 0$ and $A = 0$,

$$\left\{\begin{array}{l}a=0,\\ A=0,\end{array}\right. \Leftrightarrow \left\{\begin{array}{l}(1-\frac{3b_i}{4})B^2=0,\\ A=0,\end{array}\right. \Leftrightarrow \left\{\begin{array}{l}B=0,\\ A=0,\end{array}\right.$$
$$\Leftrightarrow \left\{\begin{array}{l}1+\Delta=0,\\ \frac{\eta_i}{\beta_{\perp i}}-(1-\eta_i)=0,\end{array}\right. \quad (19)$$

(19) can never be satisfied, then, there is no unstable domain, providing we use small argument expansion of $\Gamma_{0,1}(b_i)$ and $Z(\xi_i)$.

We can also contour plot (see FIG.1) the $a = 0$ boundary and $A = 0$ boundary to show whether there is a region satisfy both (18) and $A < 0$. However, these contour plots can also help to show the sizes of each kind of ranges.

We see that, indeed, none of the parameters ($\beta_{\parallel i}$, $\beta_{\perp i}$) satisfy both $a < 0$ and $A < 0$, which means that the unstable domain, if it exists, should be very very narrow. The only possibility is when $\Gamma_{0,1}(b_i)$ or $Z(\xi_i)$ cannot be expanded, i.e., $b_i \sim 1$ or $\xi_i \sim 1$. In next section, we will use Nyquist technique to prove that there is indeed no unstable domain for exciting the classical stable FH (KAW) in arbitrary parameters.

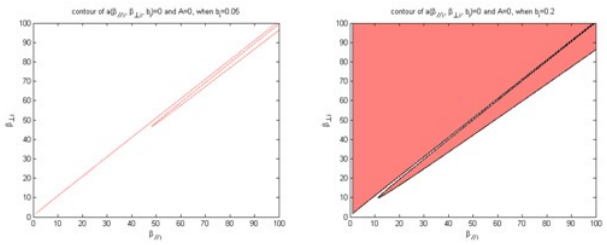

FIG. 1: Contour plot of $a = 0$ and $A = 0$.

3. Numerical solutions

Numerical solutions of (11) at FH (KAW) branch are given below,

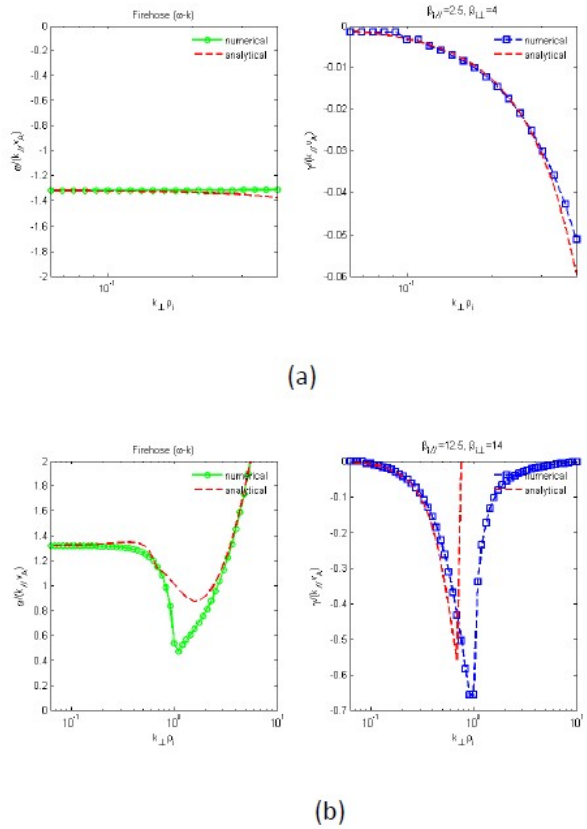

FIG. 2: Numerical solution and analytical solution (16), firehose (KAW).

FIG.2 shows, the analytical and numerical solutions are agreed very well. The coupling of MM is weak, and mainly brings KAW (FH) a damping.

B. Firehose correction to mirror mode

At this case,

$$\left[\frac{2\eta_i}{\beta_{\perp i}} - \lambda_7 - \lambda_8\right] = \eta_i \lambda_6^2 / \left[\frac{b_i}{\bar{\omega}^2}(1+\Delta) - \lambda_5\right], \qquad (20)$$

We define $\bar{\omega}_0$ be the traditional mirror mode solution (zeroth order), i.e., $\xi_{i0} = \bar{\omega}_0/\sqrt{\beta_{\parallel i}} \ll 1$, and

$$\xi_{i0} Z(\xi_{i0}) = \frac{\eta_i - (1-\eta_i)\Gamma_1(b_i)\beta_{\perp i}}{\beta_{\perp i}\Gamma_1(b_i)}, \qquad (21)$$

We can rewrite (20) as,

$$\xi_i Z(\xi_i) \simeq \left[\frac{\eta_i}{\beta_{\perp i}} - (1-\eta_i)\right] - \frac{\eta_i[\Gamma_1(b_i)-1]^2}{2\left\{\frac{b_i}{\bar{\omega}_0^2}(1+\Delta) - [1-\Gamma_0(b_i)]\right\}}, \qquad (22)$$

which brings just a very small correction and MM is still pure growing or damped. This means the coupling from KAW (FH) is also weak, and the traditional treatment of MM reasonable. To go further, we use the expansion $\xi_i Z(\xi_i) \simeq i\xi_i\sqrt{\pi}\left[e^{-\xi_i^2} - 2\xi_i\right] \simeq i\sqrt{\pi}\bar{\omega}/\sqrt{\beta_{\parallel i}}$. The analytical solution in FIG.3 is by solving (21) and (22) with $\xi_i Z(\xi_i) \simeq i\sqrt{\pi}\bar{\omega}/\sqrt{\beta_{\parallel i}}$, and then adding the correction term $\left[e^{-\xi_i^2} - 2\xi_i\right]$. Numerical solutions of (11) at mirror mode branch are also given.

From FIG.3(b), we can see, for mirror mode, the analytical solution is only suitable when $b_i \ll 1$, because, when $b_i >\sim 1$, $\xi_i = \bar{\omega}/\sqrt{\beta_{\parallel i}} \sim 1$. At FIG.3(c), the mirror mode assumption is totally broken when b_i is large. WHAMP result is also shown.

C. Physics Mechanism

1. *Mirror mode to firehose (KAW)*

We find from the analytical and numerical solution above, that, the correction from mirror mode to firehose (KAW) is always bring not a unstable but a damping. This seems mean that the mirror cannot excite firehose but, on the contrary, absorb energy from firehose.

It's widely accepted that the mechanism of mirror mode unstable is both the Landau type (wave-particle resonant) and the anisotropic free energy type. Then, it is physical reasonable that when mirror mode is unstable, it absorbs energy from firehose and cause which damped.

2. *Firehose to mirror mode*

Mirror mode is always pure growing or damping ($\mathrm{Re}(|\bar{\omega}|) \ll \mathrm{Im}(|\bar{\omega}|)$), even though with firehose coupling. There is a narrow range ($\beta_{\perp i} >\sim \beta_{\parallel i}$), both mirror mode and firehose are damping, which may be caused by Landau damping, similar with beam-plasma system (a range

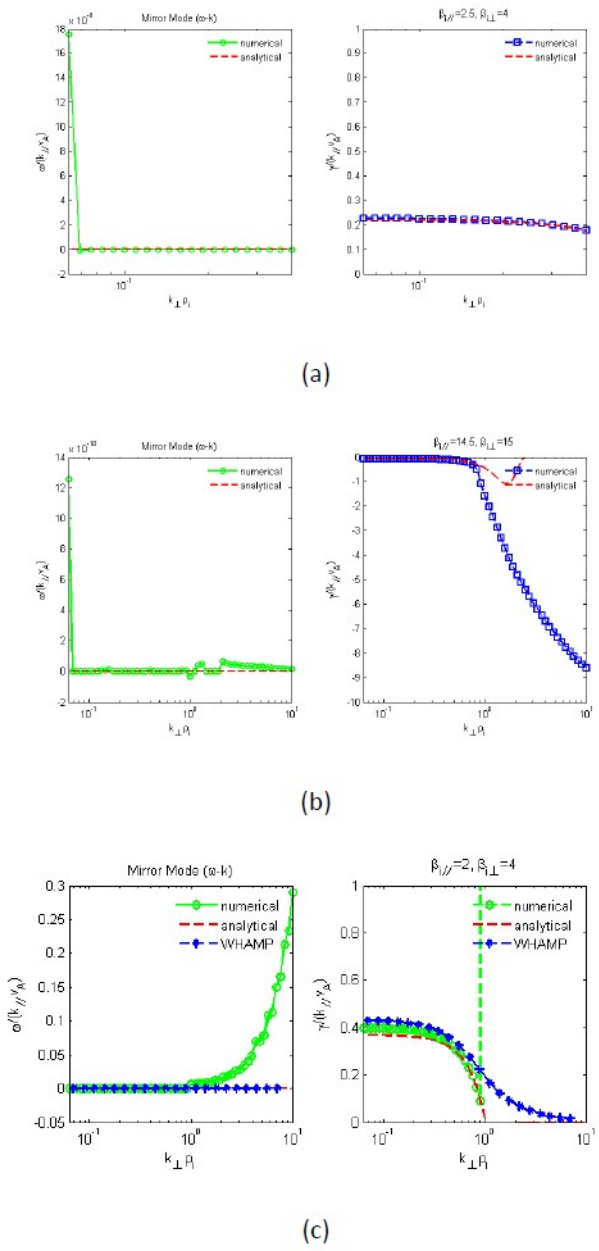

FIG. 3: Numerical solution of (11) and analytical solution from (22), mirror mode.

the free energy of non-Maxwellian distribution cannot compete to Landau damping).

V. NYQUIST STABILITIES ANALYSIS

The dispersion relation (11) can be rewritten as

$$D(\omega) = (\bar{\omega}^2 - \alpha_0)(\alpha_1 - \xi_i Z(\xi_i)) + \bar{\omega}^2 c^2 = 0, \qquad (23)$$

where

$$\alpha_0 = \frac{b_i}{1-\Gamma_0(b_i)}(1+\Delta), \alpha_1 = \frac{\eta_i}{\beta_{\perp i}\Gamma_1(b_i)} - (1-\eta_i),$$
$$c^2 = \frac{\eta_i[\Gamma_1(b_i)-1]^2}{2\Gamma_1(b_i)[1-\Gamma_0(b_i)]}. \quad (24)$$

Classical results of firehose and mirror mode instabilities,

$$\text{Firehose}: \begin{cases} \text{stable}: \alpha_0 > 0, \\ \text{unstable}: \alpha_0 < 0. \end{cases};$$
$$\text{Mirrormode}: \begin{cases} \text{stable}: \alpha_1 > 0, \\ \text{unstable}: \alpha_1 < 0. \end{cases}. \quad (25)$$

For different $(\beta_\parallel, \beta_\perp)$, there are three regions: (1) $\alpha_0 > 0, \alpha_1 < 0$, mirror mode unstable region; (2) $\alpha_0 < 0, \alpha_1 > 0$, firehose unstable region; (3) $\alpha_0 > 0, \alpha_1 > 0$, both stable (damping) region.

A. Mirror mode unstable region

We use Nyquist technique to prove that when $\alpha_0 > 0, \alpha_1 < 0$(mirror mode unstable region), there is only one unstable mode (i.e., mirror mode).

$$\xi_i Z(\xi_i) = \xi_i Z_{ir} + i\xi_i Z_{ii}, \quad (26)$$

$$D(\omega) = (\bar{\omega}^2 - \alpha_0)(\alpha_1 - \xi_i Z_{ir}) + \bar{\omega}^2 c^2 - i(\bar{\omega}^2 - \alpha_0)\xi_i Z_{ii}, \quad (27)$$

When $|\omega| \to \infty$,

$$D(\omega) \to \bar{\omega}^2(\alpha_1 + 1 + c^2) > 0, \quad (28)$$

Along $-\infty < \omega_r < \infty$, at $\mathrm{Im}D(\omega) = 0$

$$\begin{cases} \bar{\omega}^2 = \alpha_0, D = \alpha_0 c^2 > 0, \\ \bar{\omega} = 0, D = -\alpha_0\alpha_1 > 0. \end{cases} \quad (29)$$

The Nyquist diagram will draw as FIG.4.

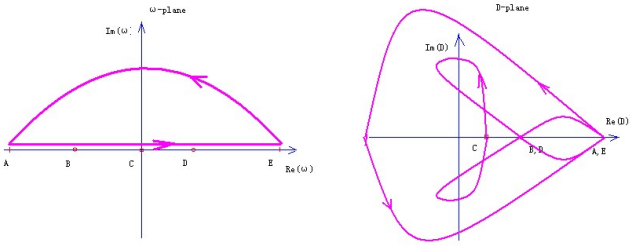

FIG. 4: Nyquist diagram of (23), mirror mode unstable region.

We see from FIG.4, the mapping in complex D-plane indeed encircle the origin point, and one time, which means there is indeed only one unstable mode. A numerical result of the mapping (partly) is shown below in FIG.5

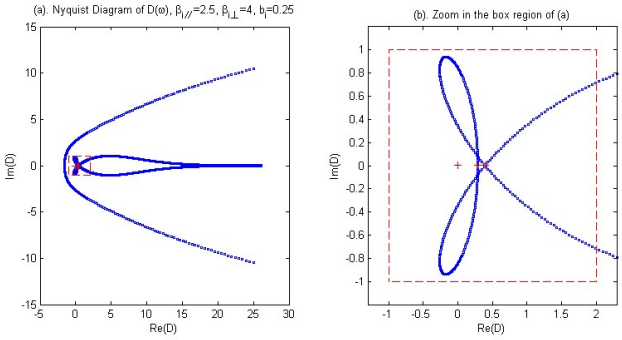

FIG. 5: Nyquist diagram of (23) verified by numerical, mirror mode unstable region.

B. Firehose unstable region

At this case $\alpha_0 < 0, \alpha_1 > 0$. When $|\omega| \to \infty$, we still have (28). And, along $-\infty < \omega_r < \infty$, $\mathrm{Im}D(\omega) = 0$ at only $\bar{\omega} = 0$, which gives $D = -\alpha_0\alpha_1 > 0$. Then, after drawing the Nyquist diagram, we can also get only one unstable mode (i.e., firehose). A result is shown in FIG.6

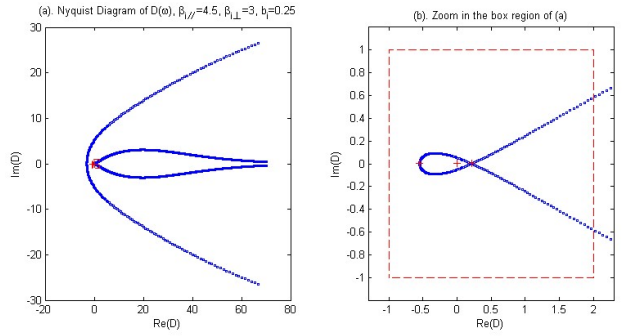

FIG. 6: Nyquist diagram of (23) verified by numerical, firehose unstable region.

C. Both stable (damping) region

At this case $\alpha_0 > 0, \alpha_1 > 0$, the analysis is similar with the mirror mode unstable case, except that in Fig4, the point $C > 0$ in D-plane should be changed to $C < 0$. Then, the mapping in complex D-plane will never encircle the origin point, which means all the solutions are stable. A result is shown in FIG.7

VI. SUMMARY

In this paper, we firstly give a general 3-by-3 gyrokinetic dispersion matrix for anisotropic bi-Maxwellain distribution plasma to discuss low-frequency hydromagnetic waves, which is suitable for arbitrary $b_{i,e}$, $\beta_{i,e}$, $\xi_{i,e}$ under

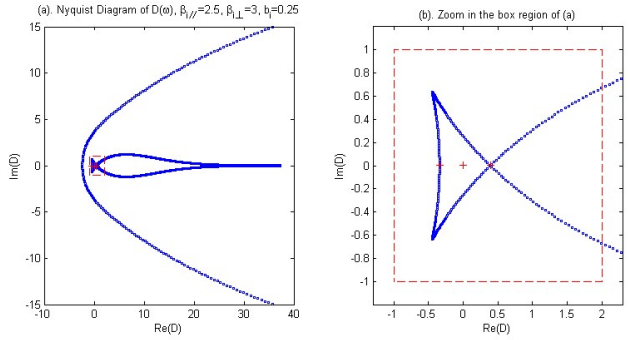

FIG. 7: Nyquist diagram of (23) verified by numerical, stable region.

the gyrokinetic ordering. This gyrokinetic matrix is useful to discuss various kinetic corrections to hydrodynamica waves. Some detailed solutions are given in [10] for isotropic plasma, e.g., analytical form of high β KAW. However, the gyrokinetic matrix can also be extended to arbitrary distribution and arbitrary species, and also to nonuniform plasma. One can do this by following the framework in [2], see e.g., [12] for 1D nonuniform plasma case. As an application example, we use this dispersion matrix to discuss the coupling of firehose and mirror mode. At the cold electron assumption, the matrix is reduced to 2-by-2, for the coupling of firehose (KAW) and mirror mode. The dispersion relation is solved both analytical and numerical, and shows consistent very well between each other. The results by the kinetic code WHAMP with all kinetic effects also show the reduced dispersion relation is appropriate. We find there exists at most one unstable solution at the $(\beta_\parallel, \beta_\perp)$ plane for arbitrary Lamor radius, and the plane can be divided into three regions: firehose unstable region; mirror mode unstable region; both modes stable (damping) region. The Nyquist analysis confirms these three regions.

VIII. APPENDIX

At this appendix, we compare the full-kinetic dispersion relation from [31] with our gyrokinetic one.

Drop the electrons term as [31] by assuming $b_e \ll 1$, (4) can be rewritten to,

$$[\eta_i DAC + \eta_i\eta_i E^2 A - \eta_i D B^2]\bar{\omega}^2 + \eta_i b_i(1+\Delta) \left[C(\eta_i D - A) + (\eta_i E - B)^2\right] = 0, \quad (30)$$

where,

$$\Delta = \frac{\beta_{\perp i}}{2b_i}(1-\eta_i)\left[1-\Gamma_0(b_i)\right] + \frac{\beta_{\perp e}}{2}(1-\eta_e),$$
$$A = \frac{Z'(\xi_i)}{2}\Gamma_0(b_i) + \tau\frac{Z'(\xi_e)}{2},$$
$$B = \frac{Z'(\xi_i)}{2}\Gamma_1(b_i) - \frac{\eta_i}{\eta_e}\frac{Z'(\xi_e)}{2},$$
$$C = \frac{2\eta_i}{\beta_{\perp i}} + 2\eta_i\Gamma_1(b_i) + 2\frac{\eta_i}{\tau_\perp} + \frac{Z'(\xi_i)}{2}\Gamma_2(b_i) + \frac{\eta_i}{\eta_e\tau_\perp}\frac{Z'(\xi_e)}{2},$$
$$D = [1-\Gamma_0(b_i)] = \lambda_6,$$
$$E = [1-\Gamma_1(b_i)] = -\lambda_7 \quad (31)$$

Dropping the $O(\delta^2)$ term $k_z^2 v_A^2/\Omega_i^2$ in [31], keep only $O(1)$ term in η and η', the full-kinetic dispersion relation in [31] can be written as [33],

$$\underbrace{-A\varepsilon'(\frac{\omega}{\Omega_i})^4}_{O(\delta^4)} + \underbrace{(2A - b_i\eta_i)(1+\Delta)\frac{k_\parallel^2 v_A^2}{\Omega_i^2}(\frac{\omega}{\Omega_i})^2}_{O(\delta^4)} + \underbrace{\frac{k_\parallel^2 v_A^2}{\Omega_i^2}(1+\Delta)\frac{k_\parallel^2 v_A^2}{\Omega_i^2}(1+\Delta)\left[(b_i\eta_i - A)\right]}_{O(\delta^4)} + \underbrace{\left[b_i\eta_i\frac{AC}{\eta_i} + AE^2 - \frac{1}{4\eta_i}b_i B^2\right](\frac{\omega}{\Omega_i})^2}_{b_i O(\delta^2)} + \underbrace{\frac{k_\parallel^2 v_A^2}{\Omega_i^2}(1+\Delta)b_i\eta_i\left[\frac{1}{\eta_i}C\left(D - \frac{A}{\eta_i}\right) + \left(E - \frac{B}{2\eta_i}\right)^2\right]}_{b_i O(\delta^2)} = 0 \quad (32)$$

where,

$$\varepsilon' = \frac{1 - I_0 e^{-\lambda_i}}{\lambda_i} - 2\lambda_i\sum_{n=1}^{\infty}\frac{2\left(I_n e^{-\lambda_i}\right)'}{n^2} \sim O(1) \quad (33)$$

Dropping the high order $O(\delta^4)$ terms in (32), we get exactly the same result as the gyrokinetic result (30). We find in (32) when $b_i \sim k_\parallel^2 v_A^2/\Omega_i^2$, the $b_i O(\delta^2)$ will jump to $O(\delta^4)$!! So, we cannot drop the $O(\delta^4)$ in (32) when $b_i \to 0$. This is what [31] found.

In [31], the classical firehose solution is found in full-kinetic at the $O(\delta^4)$ terms, because $b_i O(\delta^2)$ terms can be dropped when $b_i \to 0 \ll O(\delta^2)$. While in gyrokinetic, the solution is found in $b_i O(\delta^2)$ terms, because we have ruled out the $O(\delta^4)$ terms by gyrokinetic assumptions. It should be just a coincidence that they give the same firehose result. The different can also be explained in another way: to get the classical firehose solution, the full-kinetic approach of [31] uses the assumption $b_i \to 0 \ll O(\delta^2)$, while the gyrokinetic approach uses $b_i \to 0 \gg O(\delta^2)$.

To discussion the fine structure of the hydrodynamica waves and instabilities, (32) can be seen as an extent version of our gyrokinetic dispersion relation, and won't go so complicated that can only be solved via numerical.

This is why we indeed have general dispersion relation for arbitrary distribution and with all kinetic effects in [28] and also can be numerical solved in very general form by WHAMP ([23], but should note that WHAMP is not suitable for strong damped waves, because the plasma dispersion function in that code is expanded via Páde approximation), but we still derive many other reduced dispersion relations to meet special desires.
